

The project was made using some systems i had made previously, the character, damage and save system were made in other older projects. Some of these systems needed some reworking or rewriting, the character system was based on the 'TopDownEngine' asset, there is a main component that keeps only the 'Abilities' that are allowed enabled, combined with a pretty simple state machine it was basically plug and play, just some changes had to be made since the movement and direction was based on 3D objects. The damage system came from the same project as the character system, but it can be used without the character component, it is completely free from other sources, though it works better with the character system, it can combine easily with other systems too. The save system is from an old project, it's idea was to take data from various sources that use an 'ID' to load the data from the cached data even if the object was not instantiated, its loaded data is available. I also added a mini library that i use to help me called 'HaroLibs'. It is a mix of small systems and helpers. The inventory system was the only one i hadn't really done before, not with the tools and knowledge i have now, it took me some time and there were bugs throughout the ending, but i believe i squashed them all, unfortunately i didn't have enough content to really push it to the limit, so i got to work with what i had, that was the inventory system, a sword and some potions, making enemies would not be a good idea since there wasn't a lot of time to refine the AI, so to make sure the potions had a reason to exist, i made the pots deal damage to player, only 2 colored pots, the sword was needed to break the pots adding the necessity to equip the sword to break the pots, making the player open the inventory, so i would hope that all the systems that were implemented would be used. All the visual assets i got from Unity asset store, there were some packages that i personally use for convenience, but all the assets that i use are free.
